RESPIRATION, n. Re^2-spi^{2}r-a′shu^{3}n. Gr., ἀναπνοή, ἀνάπνευσις. Lat., *respiratio* (from *respirare*, to breathe). Fr., *r.* Ger., *R., Athmen, Athmung, Athem.* 1. Of less recent writers, the taking up of carbon dioxide and the rejection of oxygen by the green parts of plants in sunlight; shown by Draper (1844) to be comparable to digestion, but not to r. Physiologists are now agreed that the r. of plants is identical with that of animals, and the term is used collectively for the processes of absorption of oxygen by plants, oxidation of the oxidizable organic matter (carbohydrates) in their tissues, and evolution of the products (carbonic acid and water) of such oxidation. [B, 229, 291 (a, 35); J, 40.]—**Abdominal r.** Fr., *r. abdominale* (ou *ventrale*). Ger., *Abdominalathmen, Bauchathmen.* R. In the lower forms of air-breathing animals, aerial r. is combined with aquatic r., as in frogs, or the animal may exercise either aerial or aquatic r. as inclination or necessity demands, like frogs in winter and some pulmonate gastropods. [J, 5, 11.]—**Aquatic r.** Ger., *Wasserathmung.* R. in water, *i. e.*, r. in which the respiratory membrane, branchial mucosa (gills), skin, etc., are supplied with oxygen and relieved of carbon dioxide by means of water. [J.] Cf. *Aerial r.*—**Artificial r.** Ger., *künstliche Athmung.* 1. Imitation of the natural movements of r., as by alternately drawing the arms up over the head and pressing them against the sides of the chest, thus in turn enlarging the thoracic cavity by elevating the ribs and diminishing it by depressing them, as in Sylvester's method of resuscitating asphyxiated persons. The expiration may be made more complete by pressing the abdominal wall toward the thorax at the same time that the chest is compressed. [J.] Hall's method (the so-called "ready method") of treating asphyxia consists in laying the person on the face, to allow liquids to run out from the air-passages, then turning him on one side, so as to allow of the expansion of the walls of the chest from the weight of the body having been removed from the breast. These movements are repeated fifteen times to the minute, and warm applications are made. Howard's method is by the direct application of compression to the ribs by the hands of the operator, who kneels over the patient, slowly brings his weight to bear upon the chest, compressing the ribs and costal cartilages, and then suddenly removes the pressure, allowing the thorax to expand by its own elasticity. [E.] 2. See *Forced r.*—**Blood-r.** Ger., *Blutathmung.* See *External r.*—**Blowing r.** See *Bronchial r.*—**Branchial r.** Ger., *Kiemenathmung.* R. by means of gills or branchiæ, as in aquatic animals. [J.]—**Bronchial r.** Fr., *souffle bronchique, bruit des bronches.* Ger., *Bronchialathmen, Bronchialgeräusch.* 1. A form of r. which displaces vesicular r. in certain diseases of the lungs. In inspiration it is tubal, short in duration, incomplete, and of high pitch. Expiration is as long as inspiration or longer, of greater intensity, and of higher pitch. It indicates condensed lung tissue, as in pneumonia, pleurisy with effusion, etc. [D, 1.] See also *Bronchial* MURMUR.—**Broncho-vesicular r.** Of Flint, r. which shows less of the vesicular character than the healthy respiratory murmur, less softness, higher pitch, and more of a blowing and less of an equable character. The inspiratory portion is short in duration, elevated in pitch, and variable in intensity. The expiratory portion is either absent or, if present, prolonged, higher in pitch, and often of greater intensity than the inspiratory portion, which it follows after an appreciable interval. It indicates pulmonary condensation, and may occur in phthisis, pneumonia, cancer, œdema, etc. [D, 1.]—**Buccal r.** See *Mouth*-BREATHING.—**Cavernous r.** R. accompanied by a sound like that produced by blowing into a cavity. In inspiration it is slow in its development and low in pitch; in expiration it is still lower in pitch. It indicates a cavity or a globular bronchial dilatation. [D, 1.]—**Cerebral r.** See *Nervous r.*—**Cheyne-Stokes r.** Ger., *Cheyne-Stokes'sches Phänomen* (oder *Athmungsphänomen*). An abnormal state of the r. observed when death is impending, and in certain diseases, especially of the brain, first carefully investigated by Cheyne and Stokes. [J, 55.]—**Divided r.** [Walshe]. That form of r. in which there is a distinct interval between the murmur of inspiration and that of expiration; due to dilatation of the air-cells (as in emphysema), by which the expulsion of the air is hindered. [D, 1.]—**Exaggerated r.** R. which differs from normal r. only in showing greater intensity. It may, however, become a sign of disease, in which case the excess of intensity is in expiration; in health it is in inspiration. [Walshe and Fournet (D, 11).]—**External r.** Ger., *äussere Athmung, Blutathmung.* The assumption of oxygen and rejection of carbon dioxide carried on by the blood in its passage through the lungs, branchiæ, or other respiratory membranes. The oxygen is conveyed by the blood to the entire body, and while in the capillaries the blood gives up its oxygen to the tissues and receives carbon dioxide in return. So far as general r. is concerned, the blood acts simply as a carrier of oxygen and carbon dioxide for the tissues. Considered as a tissue, however, the blood respires like other tissues. [J.] See *Tissue r.*—**Extrinsic r.** Of F. [a, 34.]—**Hollow r.** See *Amphoric* MURMUR (1st def.).—**Indirect r.** R. in which the living matter is usually in quite large masses, as in the higher animals, and the oxygen is supplied by a respiratory blood, which also removes the carbon dioxide. In this form of r. the respiratory blood is in turn supplied with oxygen and relieved of carbon dioxide by special respiratory organs (lungs or gills). [J, 55.]—**Inner r., Internal r.** See *Tissue r.*—**Interrupted r.** Fr., *r. saccadée, r. entrecoupée.* R. in which the respiratory murmur is interrupted; supposed to be caused by incomplete dilatation of the air-cells and oftenest found at the anterior surface of the apex of the right lung. In insects the air is conveyed to the tissues by the tracheæ, and the tissues respire the oxygen of the air directly, instead of from the blood as in man, etc., the walls of the tracheæ acting as a respiratory membrane. In unicellular organisms (*Protozoa*) the general surface of the body acts as a respiratory membrane, and the protoplasm respires the oxygen dissolved in the surrounding water directly. Fr., *rhubarbe* (*de Chine,* ou *de Moscovie,* ou *de Perse*) [Fr. Cod.]. Ger., *Rhabarber, Rhabarberwurzel.* Sp., *ruibarbo* (*rizoma ó tallo aéreo*) [Sp. Ph.]. 1. Of the U. S. Ph., the root of *Rheum officinale* and other undetermined species of *Rheum;* of the Br. Ph., the sliced and dried root of "*Rheum palmatum, Rheum officinale,* and probably other species, collected and prepared in China and Thibet." The botanical source of the commercial drug (see *Chinese r.*) has not been definitely ascertained, the various species supposed to yield it producing under cultivation in Europe roots lacking some of the characteristics of the Chinese drug. The differences, however, may be due to climate. R.-root contains chrysophan, rheotannic acid, emodin, a neutral substance, $C_{10}H_{12}O_4$, forming colorless crystals, several resins (see APORRHETIN and ERYTHRORRHETIN), an albuminoid principle insoluble in alcohol but soluble in water, mucilage (11 to 17 per cent.), extractive, tannic and gallic acids, sugar, starch, pectin, lignin, calcium oxalate, and various inorganic salts. All varieties of r.-root have the properties, though in a lesser degree, of the Chinese drug. It is purgative and cholagogue, and in small doses (from 5 to 10 grains) a mild laxative and stomachic tonic. It is useful in dyspepsia attended with constipation or with deficient biliary and intestinal secretions, in cholera infantum, and in chronic dysentery, and is of special value in duodenal catarrh or catarrh of the biliary ducts with jaundice and in certain skin diseases. It is also applied in powder to indolent and sloughing ulcers. It is most effectual in substance,

though the fluid extract, infusion, syrup, and tincture are also used, being combined with soap in cases in which it is necessary to counteract its astringency. 2. The genus *Rheum.* [B, 5, 180 (α, 35).] For the preparations, see the corresponding Latin forms under *Rheum.*—**Austrian r.** See under *German r.*—**Banbury r.** See under *English r.* (2d def.).—**Batavian r.** A variety of Chinese r. prepared so as to resemble Russian r. The pieces are of a less bright color than the Russian drug, and are pierced through with perforations, which are often concealed, however, by being filled with the powdered root. [B, 5 (α, 35).]—**Bucharian r.** 1. The *Rheum undulatum;* so called because formerly believed to furnish Russian r. 2. Russian r. 3. The Chinese r. of the Russians; an inferior variety of r.-root imported into Russia from Tartary. [B, 180 (α, 35).]—**Canton r., China r., Chinese r.** Lat., *rheum sinense* (seu *indicum*). Fr., *rhubarbe de Chine* [Fr. Cod.]. Ger., *chinesischer* (oder *dänischer*, oder *holländischer*, oder *ostindischer*, oder *tatarischer*) *Rhabarber.* Sp., *ruibarbo de China* [Mex. Ph.]. R.-root as now known to commerce. It occurs in cylindrical, or barrel-shaped, or plano-convex, or conical, or irregular-shaped pieces, of a peculiar aromatic odor and a bitter, astringent taste; they average about 3 or 4 inches in length and 2 to 3 inches in width, and are usually sorted as round and flat r. The pieces are somewhat shriveled on the surface, and are pierced with holes in which may be found portions of a string used to suspend the root when drying. The drug when well developed displays, if broken transversely, lines (medullary rays) arranged as an internal ring of stellate spots. When powdered, it is yellow, having a tinge of reddish-brown. It has a gritty taste when chewed, and turns the saliva yellow. There are two varieties of China r.—one, believed to be produced by the *Rheum palmatum*, having a red-grained fracture with white lattice-work veins, and the other, referred to *Rheum officinale*, a black-grained fracture with white veins ramifying longitudinally. For chemical composition and medicinal properties, see under *R.* [B, 5, 180 (α, 35).]—**Compound tincture of r.** See *Tinctura* RHEI *amara.*—**Crown r.** See *Russian r.*—**Decoction of r.** See *Infusum* RHEI.—**Dutch r.** Lat., *radix rhei hollandici.* See *Chinese r.*—**Dutch-trimmed r.** See *Batavian r.*—**East Indian r.** See *Chinese r.* and *Himalaya r.*—**English r.** 1. See RHEUM *rhaponticum.* 2. The root of *Rheum rhaponticum* and *R. officinale* cultivated in Great Britain. That from *R. rhaponticum* formerly occurred in two forms, one perforated and the other (*stick r.*) in cylinders. The finest pieces of *Banbury r.* (so called because from *Rheum rhaponticum* cultivated at Bodicott, a village near Banbury) have a good color and display brilliant pink markings when broken. The taste is more mucilaginous and astringent and less bitter than that of Chinese r., and the texture more spongy and soft. [B, 5 (α, 35).]—**European r.** Sp., *rapóntico* [Mex. Ph.]. See *English r.*, *French r.*, and *German r.*—**False r.** The *Thalictrum flavum.* [B, 275 (α, 35).]—**French r.** Lat., *rheum gallicum.* Fr., *rhubarbe de France* (ou *indigène*, ou *pontique*). Ger., *französischer Rhabarber.* R. produced in France from *Rheum rhaponticum*, *Rheum undulatum*, *Rheum compactum*, and *Rheum palmatum.* The last-named species, according to Guibourt, affords a root more closely resembling the Chinese drug, but it has been least cultivated, owing to the liability of the central root to premature decay. Except in the vicinity of Avignon and in a few other places, the cultivation of r. in France has been abandoned. [B, 180 (α, 35).]—**Garden r.** The *Rheum rhaponticum*, *Rheum palmatum*, *Rheum undulatum*, or hybrids of these, cultivated for their edible leaf-stalks. [B, 5 (α, 35).]—**German r.** R.-root produced at Austerlitz and Auspitz in Moravia, from *Rheum compactum* and, according to Hanbury, *Rheum rhaponticum;* at Ilmitz, Kremnitz, and Frauenkirchen in Hungary from *Rheum rhaponticum;* and in Silesia from *Rheum australe.* Moravian r. is said to be nearly equal, medicinally, to Chinese r. [B, 18 (α, 35).]—**Himalaya r.** A variety produced by *Rheum australe*, *Rheum spiciforme*, *Rheum moorcroftianum*, etc.; said to be nearly equal to Russian r. as a purgative, and superior as an astringent and tonic. [α, 35.]—**Indian r.** See *Chinese r.* and *Himalaya r.*—**Medicinal r.** See *R.* and RHEUM *officinale.*—**Moravian r.** See under *German r.*—**Muscovitic r.** See *Russian r.*—**Persian r.** See *Turkey r.*—**Poor man's r.** The *Thalictrum flavum.* [B, 19, 275 (α, 35).]—**Red resin of r.** See ERYTHRORETIN.—**Rhapontic r.** See RHEUM *rhaponticum* and *French r.*—**R. yellow.** Fr., *jaune de rhubarbe.* The coloring principle of r. The perforations are large, but usually do not extend entirely through the pieces, having been made for inspection only. The powder of this has not the brownish tinge of that of the Chinese drug. [B, 180 (α, 35).]—**Stick r.** See under *English r.* (2d def.).—**Taschkend r.** A variety of Russian r. of inferior quality brought into Russia by way of Taschkend. [B, 5 (α, 35).]—**Trochiscs of r.** See *Tabellæ de* RHEO.—**Turkey r.** Originally, r. that reached Europe through the ports of Aleppo, Tripoli, Alexandria, and Smyrna. After its disappearance from commerce the term was transferred to Russian r., with which it was probably identical in botanical origin. [B, 18, 180 (α, 35).]—**White r.** Lat., *radix rhei albi, radix rhei imperialis* (1st def.). Fr., *rhubarbe blanche.* Ger., *weisser Rhabarber.* 1. RIB, n. Ri^{2}b. Gr., πλευρά, πλευρόν. Lat., *costa*. Fr., *côte*. Ger., *Rippe*. 1. One of the long, flat curved bones with the concavity inward which extend ventrally from the vertical column. Their anterior or ventral extremities are united in the thoracic region by means of the sternum and costal cartilages, and elsewhere are free. They constitute the pleurapophyses of a typical vertebra, and are usually confined to the dorsal and abdominal regions. The vertebral extremities, or heads, are somewhat thickened, and articulate with the bodies of two adjacent vertebræ, the articular surfaces usually being separated by the intervertebral ridges. On the lower margin, separated from the head by a slight constriction, the neck, is the tubercle, which articulates with the transverse process of the lower of the two vertebræ with which the r. articulates. Slightly anterior to the tubercle is the angle, at which point the bone curves more sharply. On the inner aspect of the lower border is a groove for the intercostal vessels and nerves. The anterior extremity is concave for the reception of the costal cartilage. Each r. is twisted upon itself, causing the vertical position behind to be oblique in front. In man the ribs are normally twelve in number on each side, seven true and five false. 2. A r. and its costal cartilage regarded as a unit. [L, 31, 142, 153, 332.] 3. [a, 35.]—**R. americanus.** See JATROPHA *curcas*.—**R. communis.** Fr., *ricin (commun)*, *bois de carapat*, *palma Christi*. Ger., *gemeiner Wunderbaum*, *Christuspalme*. Castor-bean, castor-oil plant, palma Christi, the κίκι, or κρότων, of Dioscorides: a native probably of the East Indies and Africa, now widely distributed through cultivation in most tropical and many temperate countries. An annual herb in the temperate latitudes of North America and Europe, it is a shrub or small tree in the warmer regions of the Mediterranean, and in some tropical countries attains a height of 40 feet. Some 16 more or less well-marked forms, some of which are regarded by many botanists as distinct, are maintained by Müller to be one species. The fruit is a capsule of three cells, each cell containing a smooth, shining, ash-colored or grayish seed, of a compressed, ellipsoidal shape, marbled with reddish-brown spots and veins. These seeds (castor-seeds) contain an acrid, probably volatile, emetic, powerfully purgative principle, and yield castor-oil. In India, where this oil is extensively produced, there are two varieties of the plant, known respectively as *R. communis fructibus majoribus* and *R. communis fructibus minoribus*, and the latter is thought to furnish the better product. The oil of the large-seeded variety is said to have a heavy, unpleasant odor and a darker color, and is used chiefly in veterinary practice and for burning. The oil of the small-seeded variety is used not only for the purposes referred to under castor-oil (*q. v.*), but in cutaneous and rectal diseases and as an anthelminthic. The leaves are used as a galactagogue, either applied to the breasts, or given internally; they are also used in skin diseases, abscesses, and ophthalmia. A decoction of the root is used in flatulent colic, for nephritic pains, and in asthma, and the root-bark is said to be powerfully purgative. The plant is cultivated in Germany for the production of silk, one species of silkworm (*Bombyx Arrindi*) requiring its leaves as food. [B, 175, 180, 185, 314 (a, 35).] Cf. [B, 316 (α, 35).]—**S. mesentericus.** A species destroying fruit acids. It forms on fermented liquids a rather strong scum which Nägeli calls the mesenteric skin (Ger., *Gekrösehaut*) because it is folded like the mesentery. [α, 35.]—**S. minor.** Ferment of bread. It resembles *S. cerevisiæ*, but the cells are somewhat smaller. [B, 316 (α, 35).]—**S. mycoderma.** A species consisting of oval, elliptical, or cylindrical cells from 6 to 7 μ long by 2 to 4 μ thick, forming very branching chains, occurring on fermenting liquids as a scum known as vinegar ferment or flowers of beer (or wine), though, according to Nägeli and others, it is not the cause of acetic fermentation (see BACTERIUM *aceti*). It is found on fermenting wine, especially if poor in alcohol, on beer (see under MYCODERMA *of beer*), on fruit-juices, and on sauerkraut. The asci attain a length of 20 μ and contain each from 1 to 4 sporidia. Some identify it with the *Oidium albicans*, from which it differs, however, according to Flügge, in its cells being more elliptical or spindle-shaped, by inducing but very slight fermentation with simultaneous death of the cells, by the ready development of spores, and by not producing thrush when inoculated on the crop of fowls. According to Seynes, this or a related organism is found in diabetic urine. These joints form lateral, roundish, or oval daughter-cells. 5 μ to 6 μ in length. The sporidia, 2 to 4 in each ascus, are 2 μ in diameter. [B, 238, 316 (α, 35).]—**S. psoriasis.** An organism occurring in the human scalp, consisting of round cells, from 28 to 30 μ in diameter, invested by a double membrane, and arranged in from sixes to eights in chains. Reessi.** A species occurring, along with *S. apiculatus* and *S. ellipsoideus*, in the fermentation of red wine. Each ascus contains 4 sporidia arranged in a single line. [B, 316 (α, 35).]—**S. sphæricus.** 1. Of Saccardo, a species found in Germany and northern Italy, in the form of small, crowded, or confluent dirty-white heaps, on fermenting tomatoes. The conidia are perfectly spherical, 5 to 6 μ in diameter, arranged in branching, variously bent chains, and often intricately twisted into balls. The basal cells of the colonies are oblong or nearly cylindrical, and from 10 to 15 μ in length by 5 μ in breadth. 2. The *S. capillitii*. [B, 238, 316 (α, 35).]—**S. tyricola.** A ferment occurring in cheese, forming round conidia 3 to 4 μ in diameter. It resembles *S. minor*. [B, 316 (α, 35).]

SACCHAROSE, n. Sa^{2}k′a^{2}r-os. Fr., *s.* Ger., *S.* A carbohydrate, $C_{12}H_{22}O_{11}$, derived in large quantities from *Saccharum officinarum*, *Sorghum saccharatum*, *Beta vulgaris*, *Acer saccharinum*, and the stalks of Indian corn. In small quantities it is found in the juices of many fruits, grasses, roots, and flowers. It occurs either as large transparent prismatic crystals (rock-candy, sugar-candy), as small, white, prismatic, crystalline granules, or as an amorphous vitreous mass (barley-sugar). It has an agreeable, very sweet taste, and is completely soluble in water, only slightly soluble in alcohol, insoluble in ether. It melts at 160° C., at 200° C. is converted into caramel, and at a higher temperature decomposes into various volatile empyreumatic principles and carbon. Its aqueous solution has a specific dextrorotary power of 73·8°. In chemical structure, s. is a doubly tetratomic or an octatomic alcohol, and at the same time a double aldehyde. It stands in the same relation to the carbohydrates of the formula $C_6H_{12}O_6$ (glucoses) that ether does to alcohol. The term is also applied generally to all carbohydrates of the formula $C_{12}H_{22}O_{11}$. [B, 4, 9.]

Ph. that of *Smilax medica.* Other imperfectly known species, such as *Smilax papyracea* and *Smilax syphilitica*, are also said to be sources of the commercial drug. The roots are cylindrical, fleshy, plump when fresh, and more or less wrinkled longitudinally when dried, have a thick amylaceous bark, are often beset with thread-like rootlets (beard) of

nearly uniform size, and grow from a thick knotty short root-stock (called *chump* by the druggists and ordered to be rejected by the U. S. Ph.). They are readily split in the direction of their length owing to the longitudinal fibres of which their ligneous portion is composed. S. displays on cross-section a white central medulla, inclosed by a woody zone of closely packed fibro-vascular bundles with scalariform vessels and lignified prosenchymatous cells. This zone is surrounded by a circle (nucleus sheath) of small cells forming a brown ring between which and the epidermis occurs a tissue (the bark) composed of parenchymatous cells often loaded with starch granules and rhaphides. S. has a marked odor only in decoction. If chewed for some time, it leaves an unpleasant acrimonious impression in the mouth and throat. Though it contains starch, resin, etc., it is believed to owe whatever medicinal properties it may possess to parillin (*q. v.*). It is used in syphilis, chronic rheumatism, scrofula, skin diseases, etc. Its value as an alterative is very doubtful. Ph.]. A gum-resin obtained by incision from the root of *Convolvulus scammonia.* The pure product, dried by exposure to sun and air, is a transparent, brittle substance, breaking with a vitreous, shining fracture. In the fragment it is pale yellowish-brown, and in powder of a light-buff color. It yields by treatment with ether over 88 per cent. of soluble matter, the residuum being almost colorless. If not kept quite dry, it usually becomes moldy, and in course of time develops at the surface a white, crystalline, cauliflower-like efflorescence the chemical nature of which is not known. Most of the s. of the U. S. markets is in circular cakes, 6 inches or less in diameter, and from ½ to 1½ inch or more thick in the centre, dark olive or dark ash externally. and lighter internally. When fractured, it exhibits usually a finely porous structure. It has a peculiar cheesy smell, and a taste which, though slight at first, leaves a bitterish, acrid sensation. When triturated with water, it gives to the latter a greenish, milky appearance. S. has cathartic properties, due to the presence of jalapin. As its tendency is to gripe, it is usually given with other cathartics, or in emulsion with mucilage, almonds, or some other demulcent. It was used by the ancient Greeks and Arabians not only as a purgative, but externally in various skin diseases. [B, 5, 18, 180 (α, 35).]—**Aleppo s.** Lat., *scammonium halepense* [Pruss. SELENIUM (Lat.), n. n. Se^{2}l-en(an)'i^2-u^{3}m(u^{4}m). From σελήνη, the moon. Fr., *sélénium*. Ger., *Selen*. A non-metallic element discovered by Berzelius in 1817. It occurs in nature in combination with sulphur and with metals in many minerals. Ordinary, or soluble, s. is either a bright-red powder or a black micro-crystalline powder, soluble in carbon disulphide, and crystallizing from its solution in dark-red monoclinic crystals. When melted and quickly cooled it forms a dark-colored, translucent, vitreous, brittle substance. When melted, cooled to 210° C., and maintained at this temperature for some time, soluble s. is transformed into so-called metallic s., or insoluble s., a granular, crystalline mass, insoluble in carbon disulphide. S., when sublimed, gives off a dark-red vapor, which condenses into the so-called scarlet flowers of s. In composition s. is usually bivalent, replacing two atoms of hydrogen, but acts as a quadrivalent or sexvalent radicle. In the formation of its

compounds it presents a strong analogy with sulphur. Symbol, Se; atomic weight, 79. White (or salad) mustard (plant), charlock ; a species indigenous probably to the more southern parts of Europe and to western Asia. The yellowish seeds, larger than black-mustard seeds and having a testa which contains a mucilaginous substance, have a composition like that of black mustard, but in place of sinigrin contain sinalbin, which in presence of water is acted on by the myrosin (in which they are richer than black mustard-seed) and splits up into acrinyl sulphocyanate, sinapine sulphate, and sugar. Hence white mustard yields no volatile oil. It is, however, a powerful rubefacient, and is usually employed in the form of the flower mixed with that of black mustard. 2. Of the U. S. Ph., the seed of *S. alba* (1st def.). [*a*, 35.]—**S. arvensis.** Fr., *moutarde sauvage* (ou *des champs*), *joltes*, *navette des sérins*, *rosse*, *russe*, *sauve*, *sendre*. [*a*, 35.]—**S. juncea.** See BRASSICA *juncea*.—**S. nigra.** Fr., *moutarde noire* [Fr. Cod.], *semence de moutarde* [Fr. Cod.] (2d def.). Ger., *Senfkohl* (1st def.), *schwarzer Senf* (oder *Senfsamen* [2d def.]). Sp., *mostaza* [Mex. Ph.] (2d def.). 1. Black (or brown, or red) mustard (plant), the νάπυ of Theophrastus and σίναπι of Dioscorides ; an herb growing spontaneously over a large part of the Old World and naturalized now in both North and South America. It bears numerous smooth, erect pods containing spherical or slightly oval, minutely pitted, blackish-brown or reddish-brown, pungent seeds. These seeds, the *s. nigra* of the U. S. Ph., or black mustard, contain cellulose, sulphur, nitrogen, albuminoids, etc., and over 20 per cent. of a greenish-yellow fixed oil consisting of the glycerin compounds of stearic, oleic, and erucic acids. They also yield by distillation with water mustard-oil (2d def.), which does not, however, pre-exist in the seeds, but is developed by the action of water on two peculiar compounds, sinigrin and myrosin, the latter, an albuminoid ferment, splitting up the sinigrin into the essential oil, a potassium salt, and sugar. Black mustard is chiefly used as a rubefacient in sinapisms. The flour is often used as an emetic, especially in narcotic poisoning. The volatile oil is also a powerful rubefacient. It has been used internally in colic, but in overdoses is a dangerous poison. 2. Of the U. S. Ph., black (or brown, or red) mustard (seed), the seeds of *S. nigra*. [*a*, 35.]—**S. nigræ semina, S.** (**semina**). See *S. nigra* (2d def.).—**Spiritus s.** Ger., *Senfspiritus*. Sp., *alcohol de mostaza* [Sp. Ph.]. Ph.] (100 [Austr. Ph., Hung. Ph., Roum. Ph., Sp. Ph.]) of 90-per-cent. alcohol. [*a*, 38.]
